

ABAC & ReBAC

- **Attribute-Based Access Control (ABAC)** is becoming more common and more important, due to its **flexibility** and **ease of administration**, especially for **complex, dynamic policies**.
- **ABAC policies** contain **rules** granting **permissions** based on **attributes** of users and resources.
- **Relationship-Based Access Control (ReBAC)** extends ABAC with **relationships** between entities (subjects, resources, ...) which can be **chained together** in **path expressions**.
 - **Example rule (informal)**: A technician can view tasks associated with active contracts for customers of her department.

Project Goals

- **Access control policies** are increasingly **large, complex, decentralized, and dynamic**.
- Administrators need better tools that help them **develop correct policies**.
- This project is developing **new techniques** for **policy mining** and **policy analysis**.

Managing ABAC & ReBAC Policies

- **Administrative policy** controls changes to the access control policy. Essential for decentralized management of policies, e.g., in large companies.
- We express administrative policies for ABAC (and ReBAC) as **rules** that control addition and removal of **rules** and changes to **attributes** (and **relations**).
 - We define a **strictness order** on rules and specify in the policy the **least strict rules** that each subject may add or remove.
 - This helps **balance flexibility** and **safety**.
- We proposed the **first** general-purpose ReBAC model with a **comprehensive administrative framework**.

Mining ABAC & ReBAC Policies

- **Policy mining algorithms** can **drastically reduce the cost of migrating** from legacy access control to ABAC or ReBAC.
- They find the **highest-quality** (e.g., most concise) ABAC or ReBAC policy consistent with given ACLs (or operation logs) and attribute data.
 - They also identify and correct **noise** (errors).
 - When mining from logs, they “fill in” **missing (unobserved) permissions**.

OPERATION LOG ATTRIBUTE DATA

Time	User	Resource	Op.	User	Dept	Position
10:34	John	Store/hours	Edit	Alex	Sales	Sales Rep
10:44	Rita	Store/budget	View	John	IT	Developer
10:45	Alex	SalesLeads	Insert	Rita	Tax	Manager

HIGH-LEVEL POLICY RULES

The manager of a department can view and edit the budgets of projects in the department.
...

Analyzing ABAC & ReBAC Policies

- Interleaved sequences of **changes** by different users may **interact** in **subtle ways**.
- **Analyze** policy (including administrative policy) to expose flaws and unexpected behaviors.
- **Abductive analysis** finds **minimal conditions on initial attribute data** that allow a given goal to be reached, starting from given initial policy rules.
- We developed **first abductive policy analysis** for an ABAC framework that allows changes to **rules** and **attribute data**. Extension to ReBAC is future work.

Algorithms and Evaluation

- We developed the **first algorithms to mine ABAC and ReBAC** policies from ACLs or logs and attribute data. We explored several approaches:
 - Heuristic-guided greedy algorithm
 - Evolutionary algorithm
 - Neural networks
 - Decision trees
- Successful evaluation on two **large case studies** based on real organizations.

Broader Impacts

- **Facilitate adoption** of flexible access control models that promote security and information sharing.
- **Reduce cost** of policy development
- **Increase confidence** in policy correctness.

Mining Temporal RBAC Policies

- **Temporal RBAC** extends role-based access control to limit the **times** at which roles are enabled.
- **Periodic expressions** denote **repeating time intervals**.
- We developed **first temporal role mining algorithm** that produces **hierarchical policies** and optimizes **multiple metrics** (**policy size, interpretability, ...**).
- **Demonstrated its effectiveness** on datasets based on **real-world ACL policies**.
- **Best Paper Award, DBSec 2016**.
