

1. Motivation

1.1 Voice – An Emerging Interaction

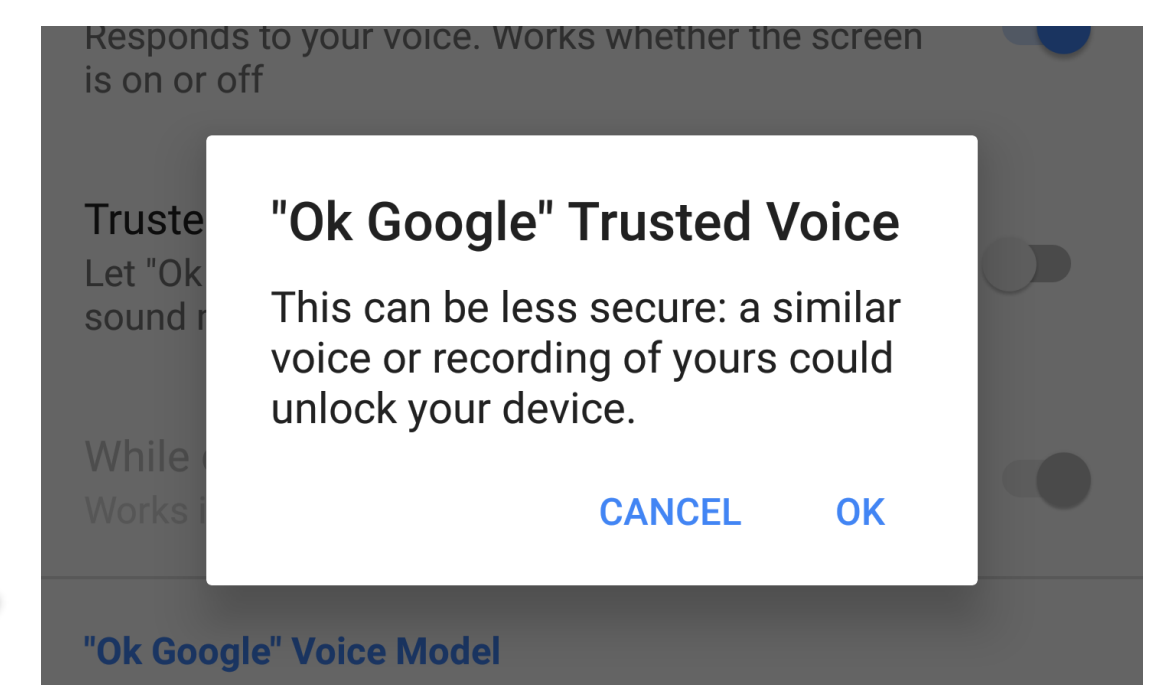

Voice assistant is a popular interaction channel with IoT devices

We need to **SECURE** the voice channel!

1.2 Limitations of Voice Assistant

1.3 Why Not Voice Biometrics?

Voice biometrics cannot be trusted!

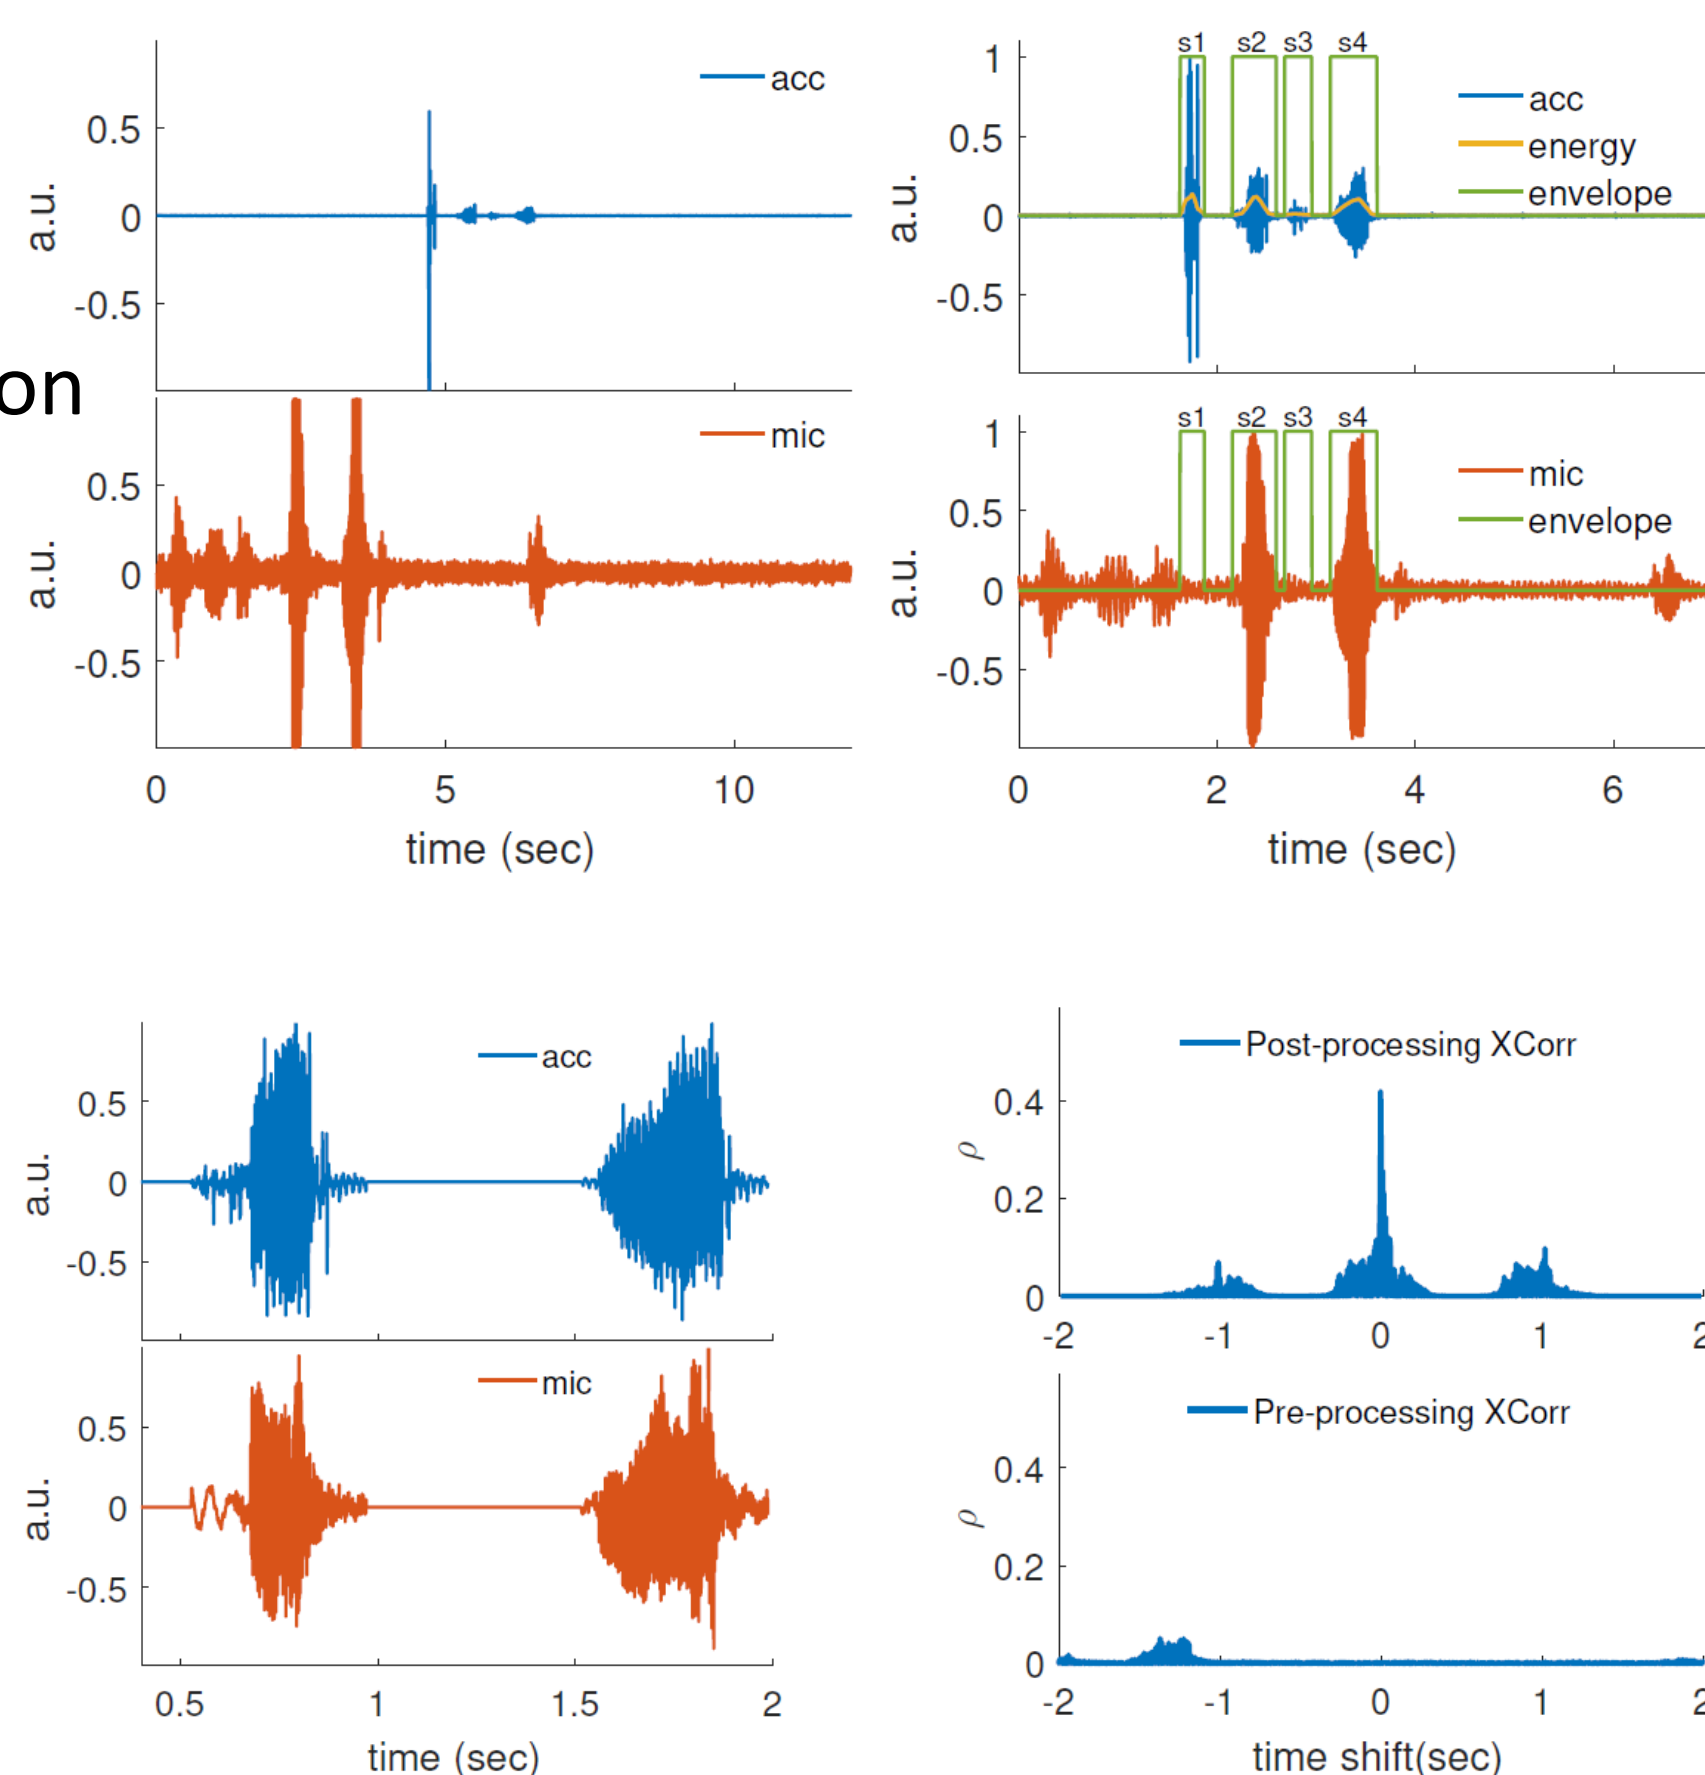

2. System Design

2.1 VAuth – Continuous Voice Authentication

2.2 Matching Algorithm

- Pre-processing
 - High-pass filter -> Re-sample -> Normalization
 - Keep segments that match human speech
- SVM-based decision making
 - Feature: the vector of cross-correlation
 - Training set: One user on all 44 English phonemes

3. Hardware & Usability

3.1 Wearable component

3.2 Usability

- Reusing wearables that are already being used everyday
 - Wear an additional device for security
 - Embed VAuth in existing wearable products

4. Evaluation

4.1 Settings

- Matching accuracy (true positive & false positives)
- 18** users speaking **30** commands under **6** scenarios
 - Three positions (eyeglasses, earbuds, necklace)
 - Two mobility patterns (still and jogging)
 - 5 languages: English, Arabic, Chinese, Korean, Persian

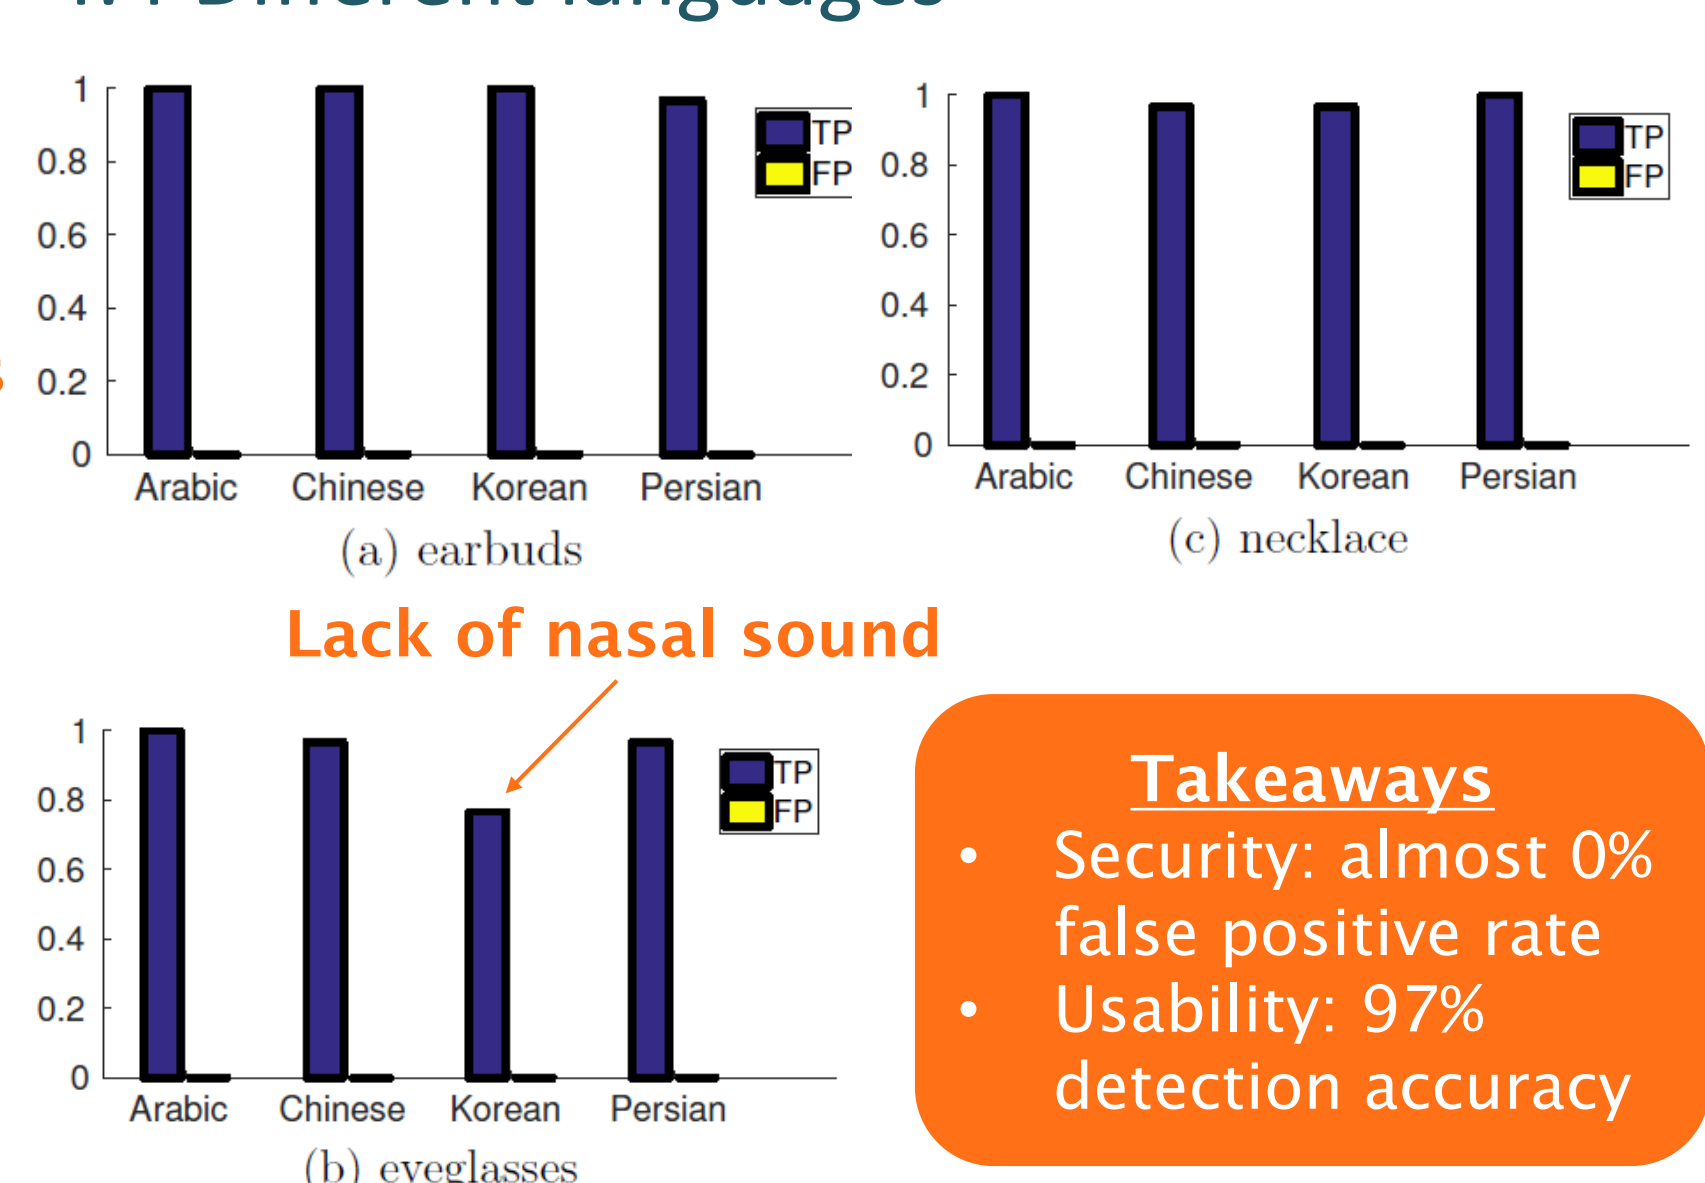

4.2 Still

4.3 Jogging

4.4 Different languages

Takeaways

- Security: almost 0% false positive rate
- Usability: 97% detection accuracy
