## Problem

- ▶ Design the attack of the **Blue force of UAV** against **Red's ground force of SAM sites and radars**.

Primary targets

Blue base

J. Borges de Sousa, T. Simsek e P. Varaiya, "Task planning and execution for UAV teams", Proceedings of the Decision and Control Conference, Bahamas, 2004.

# Threat function and path risk

- Instantaneous threat  $r(x, y; P_{A,N}) =$ 

$$\sum_{j=1}^k \sum_t \sum_{N_{tj}=0}^{\infty} \sum_{n=1}^{N_{tj}} \left[ \int_{A_j} f_t(|(x, y) - (x_n, y_n)|) |A_j|^{-1} dx_n dy_n \right] P(N_{tj})$$

$f_t(d)$  is the instantaneous threat posed at a distance  $d$  from target if type  $d$

The integral is the expected value of this threat

- Risk faced by a UAV flying at speed  $v > 0$  along a path  $\gamma$  from  $\gamma(0)$  to a destination  $\gamma(\tau)$  facing threat  $P_{A,N}$

$$\rho(\gamma; P_{A,N}) = \int_{\sigma=0}^{\tau} r(\gamma(\sigma); P_{A,N}) \frac{d\sigma}{v},$$

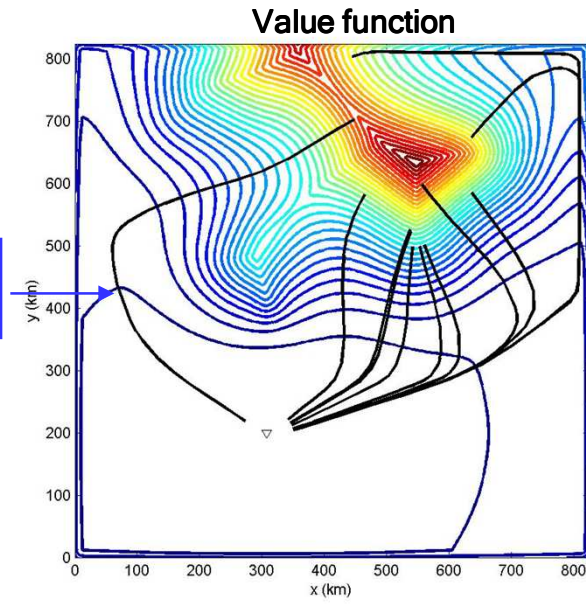

- Value function for threat  $P_{A,N}$  with  $\gamma(\tau) = (\bar{x}, \bar{y})$

$$V((\bar{x}, \bar{y}); P_{A,N}) = \min_{\gamma} \rho(\gamma; P_{A,N})$$

# Initial situation

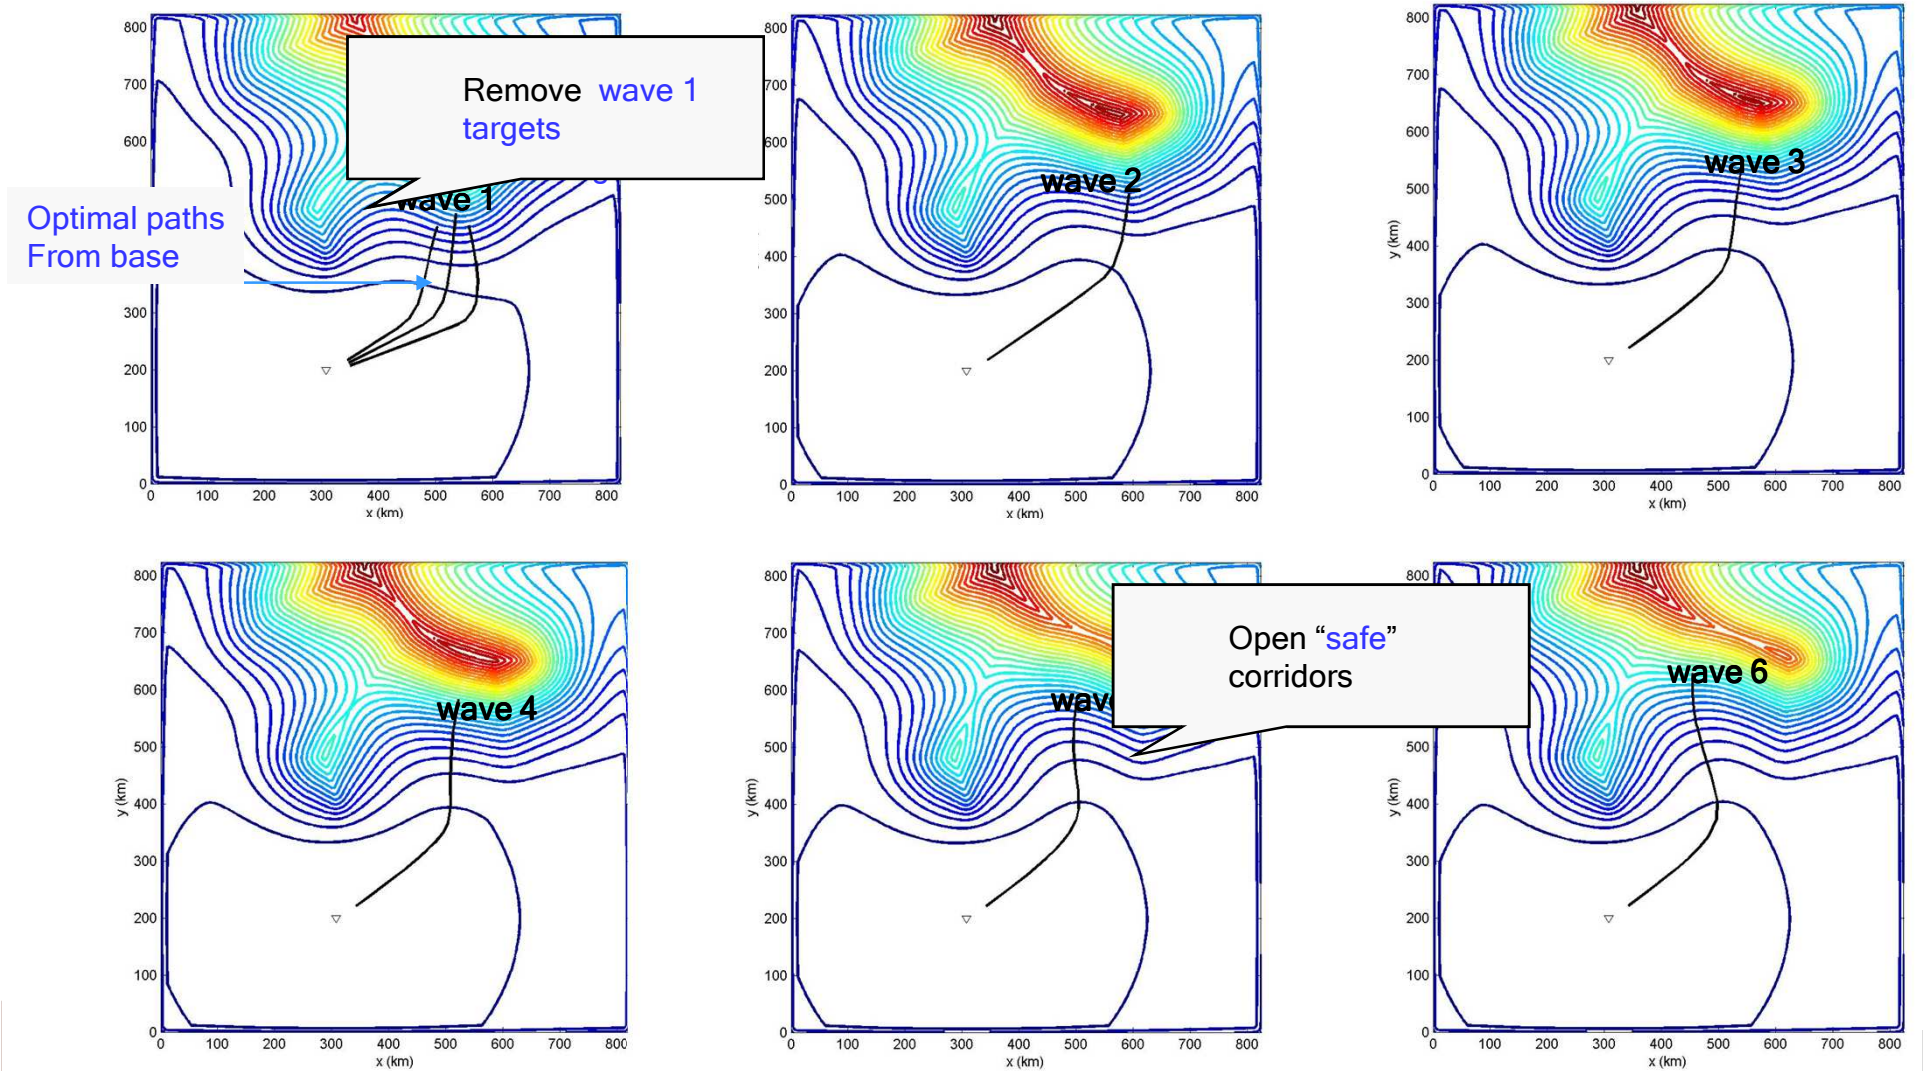

- Idea: Phased operation waves
- Resolution: 1 km
  - Number of threats: 91
  - Primary targets = {EW1-6, TEL1-4, TELS1-2}

Minimum risk paths to primary targets

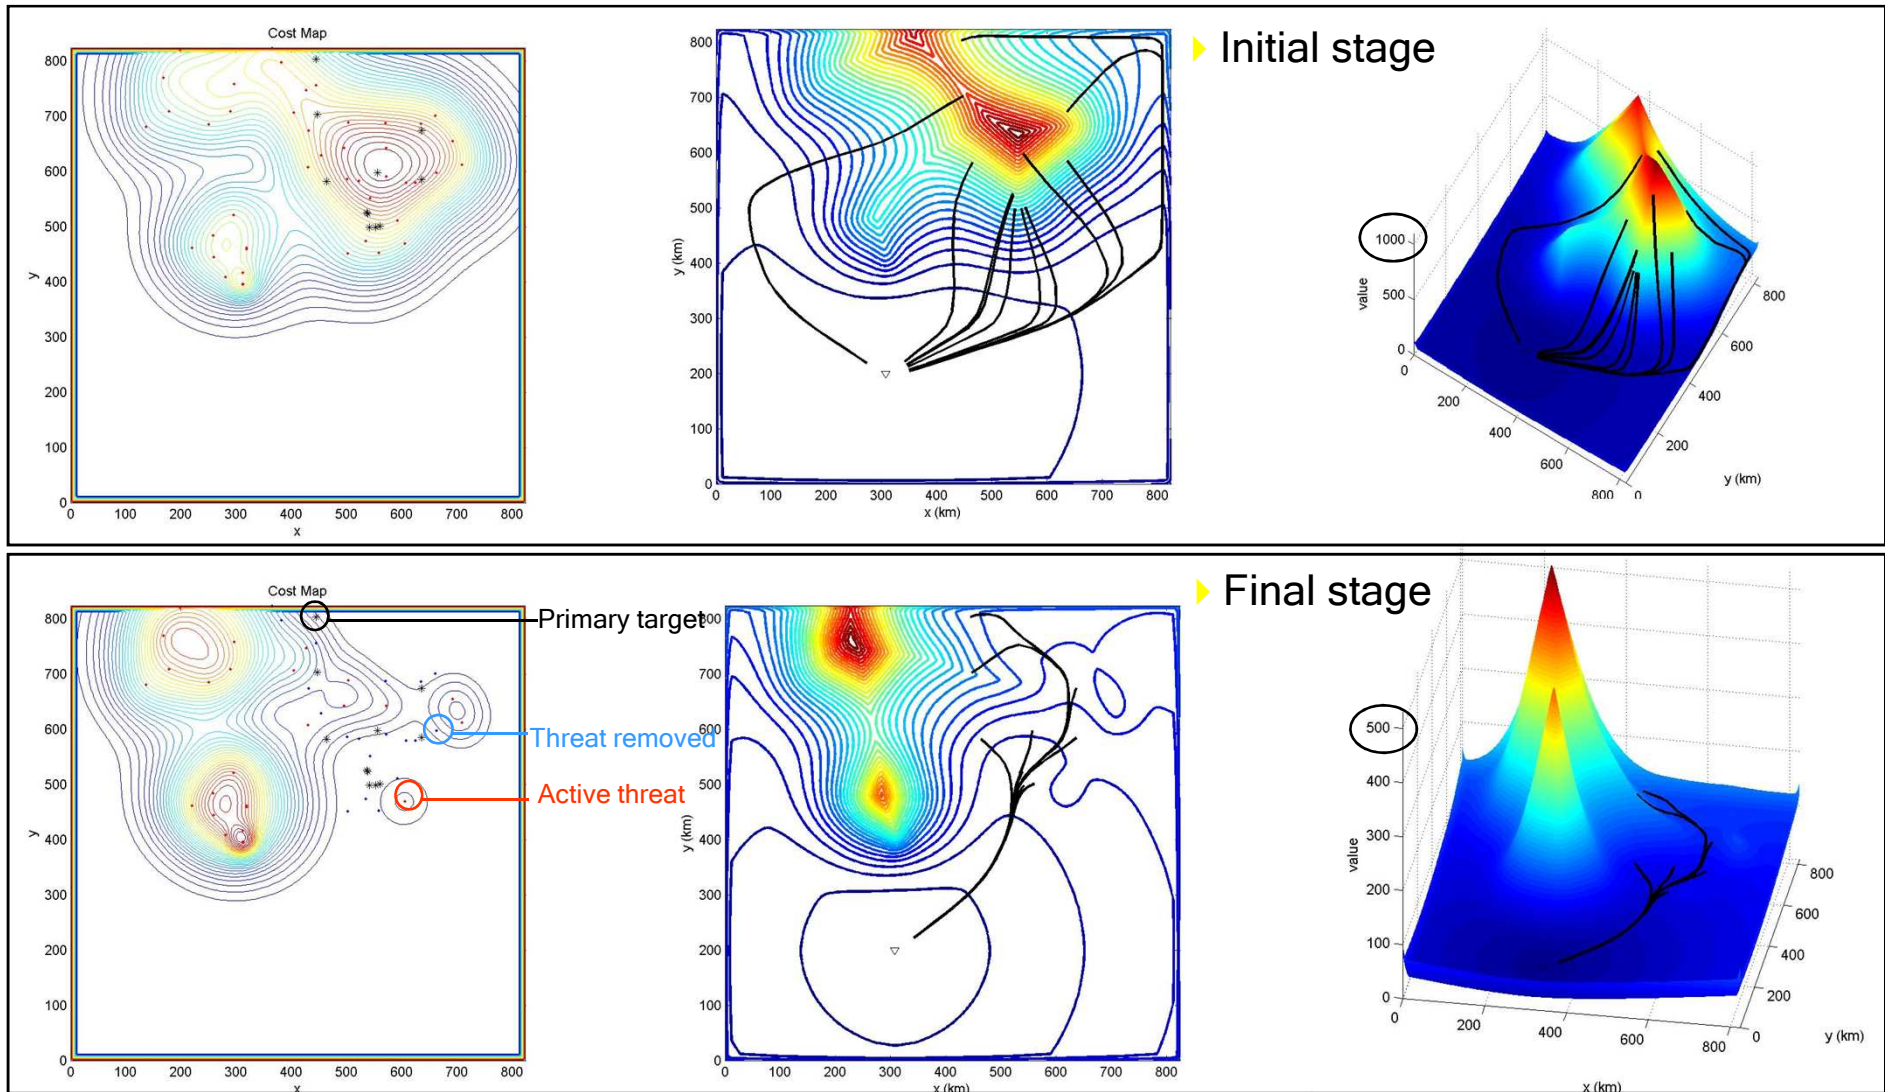

# Operator assisted procedure

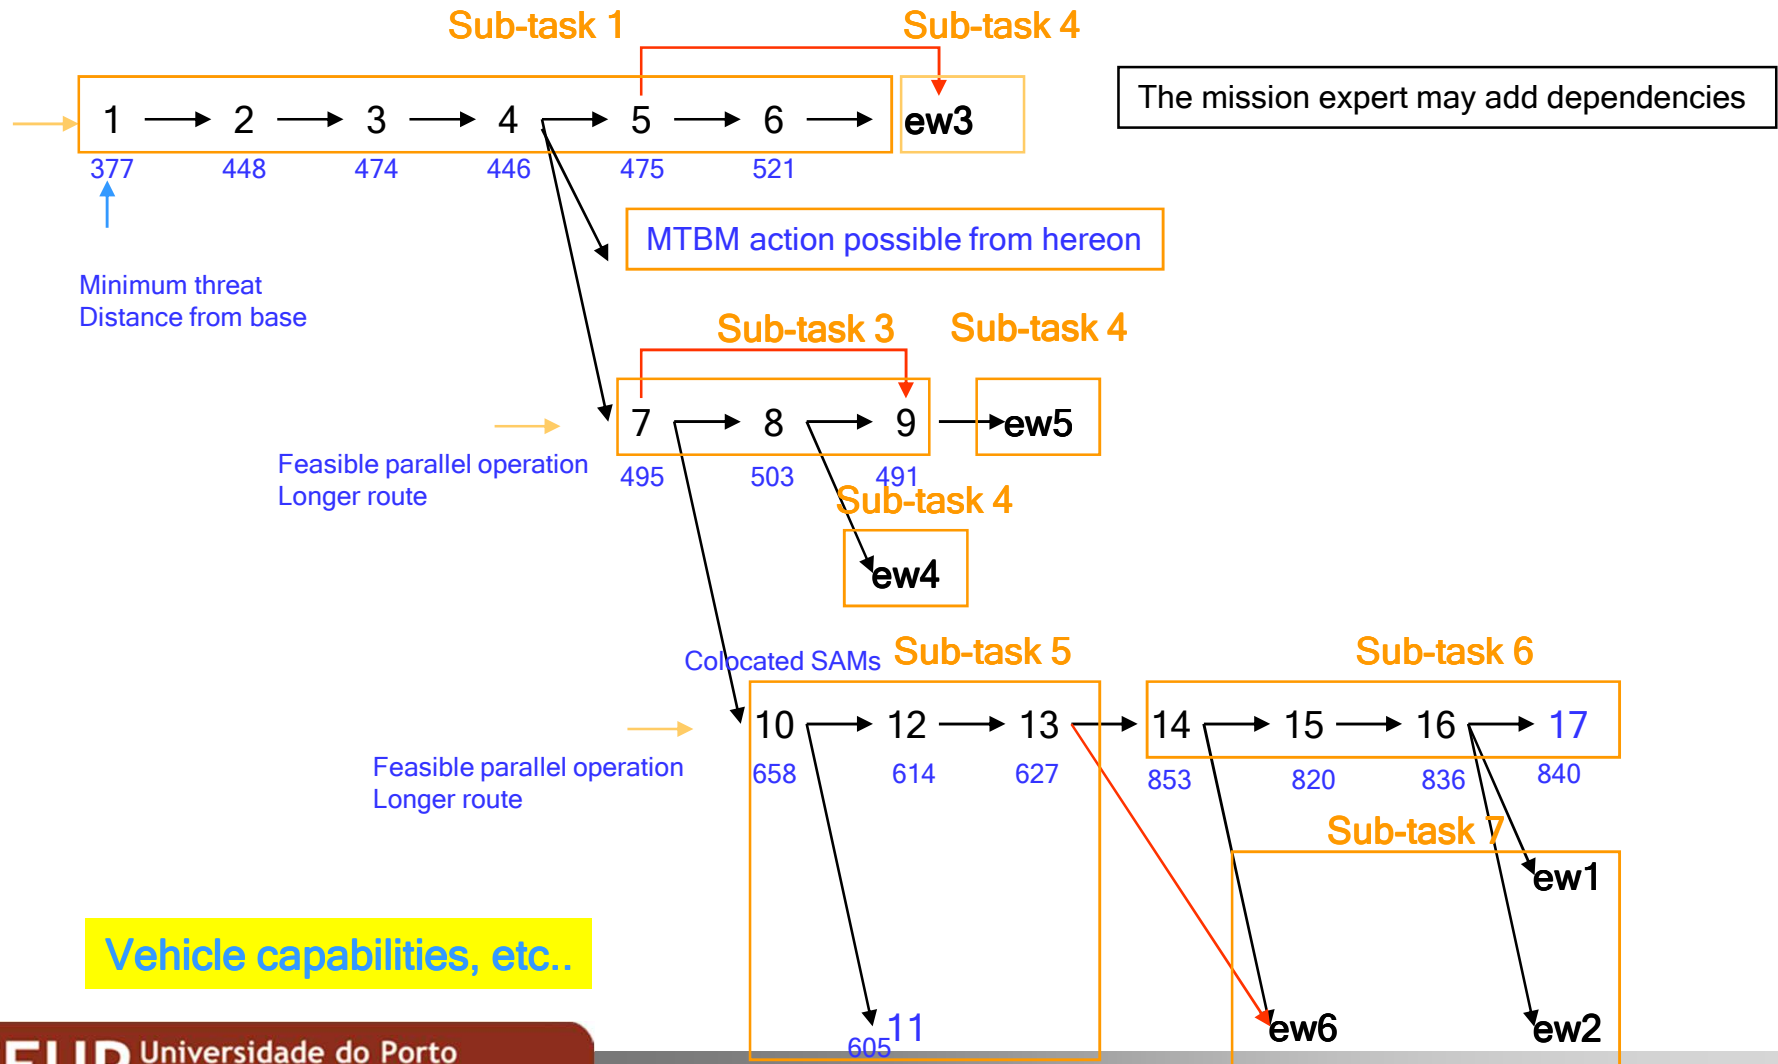

# Initial stage versus final stage

$$i = N$$

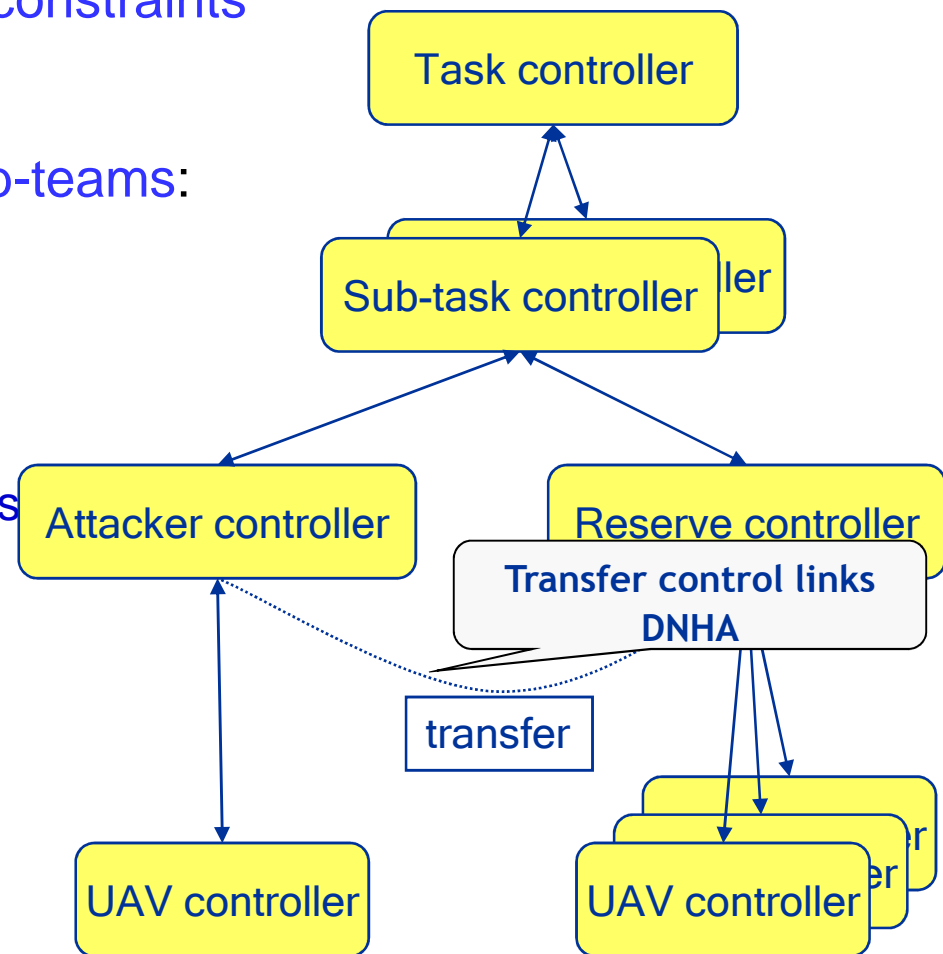

# Plan: tasks + subtasks

# Execution strategy and controllers

- Task = n sub-tasks + precedence constraints
- One team per sub-task
- Each team is organized as two sub-teams:
  - Attacker
  - Reserve
- Attacker
  - Opens corridor
  - Satisfy task precedence constraints
  - Keep executing legs until
    - Sub-task terminates
    - Eliminated or out of assets
- Reserve
  - Advance while is safe
  - Replace attackers

# Multi-vehicle search problem

- Vehicles  $v_i$ 
  - $V = \{v_1, \dots, v_n\}$
  - Each vehicle  $v_i$ 
    - Limited communication capabilities: bandwidth and range
    - Sensor for local measurements
    - Onboard computer for coordination and control
- Scalar field
  - $v = f(x, y, z, t)$
- Search algorithm
  - Repeat until termination
    - Calculate next sampling points
    - Go to sampling points

João Borges de Sousa, Karl H. Johansson, Jorge Silva and Alberto Speranzon, “A verified hierarchical control architecture for co-ordinated multi-vehicle operations”, Int. J. Adapt. Control Signal Process. 2006.

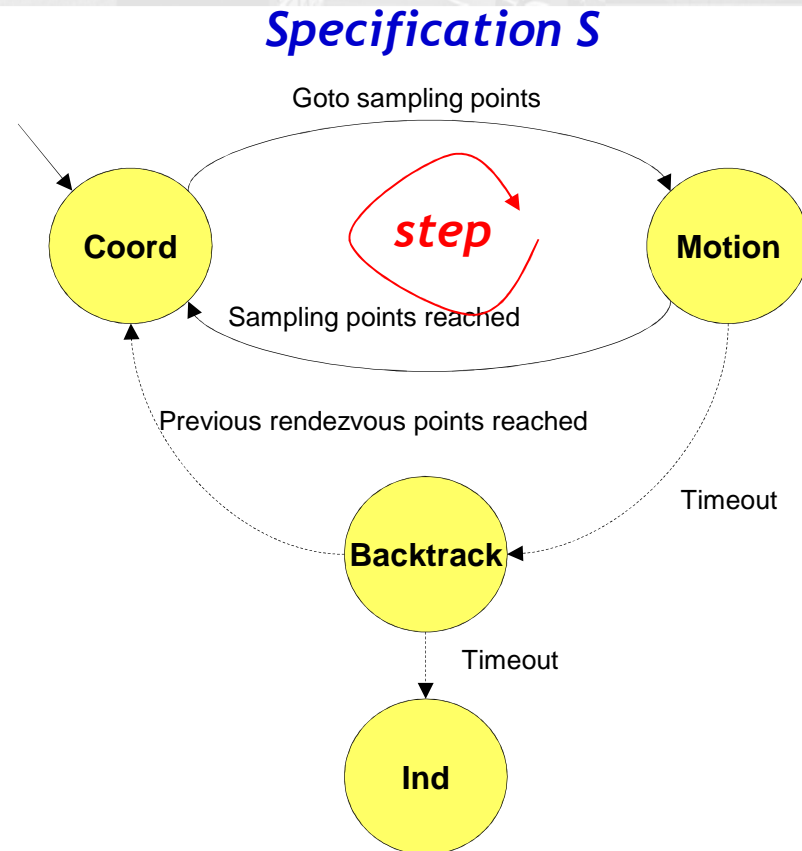

# Problem

## ■ Given

- Set of initial locations  $I$
- Measurement function  $m$
- Way-point generation function  $g$
- Termination criteria  $c$
- Specification  $S$

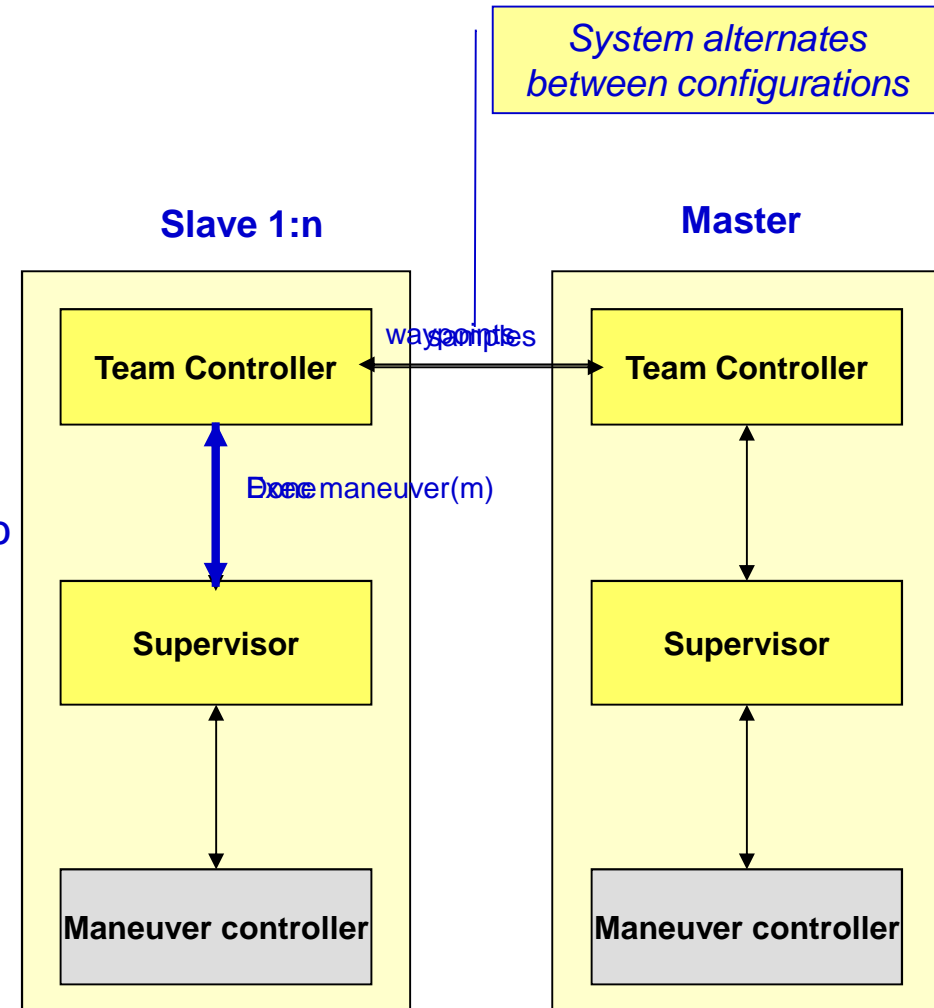

## ■ Find

- control architecture = controllers + connections such that
  - $\Sigma = V$  + control architecture satisfies the specification (simulation relation)

# Control architecture

- Team controllers
  - One master; n slaves
  - Run the coordination algorithm
  - Handle structural adaptation and reconfiguration
- Vehicle supervisors
  - Interface with external controllers
  - Makes decisions on what maneuver to execute
- Maneuver controllers
  - Implement elemental feedback control maneuvers for each AUV
  - One active at a time
  - Goto(point)
  - Hold(point)

Formal model: dynamic network of hybrid automata

# More formally...

- Formal model for team controllers

- $T = T_M || T_{S1} || \dots || T_{SN}$

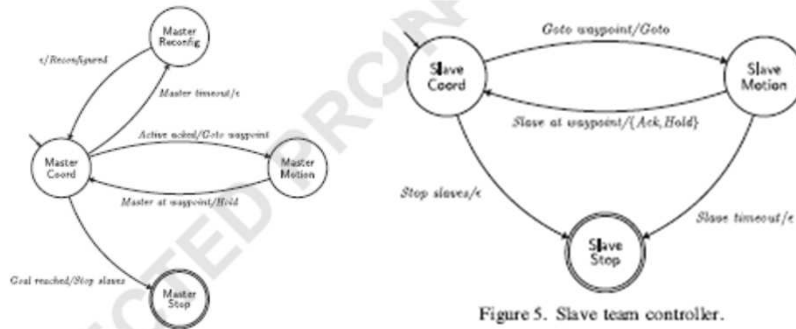

Figure 5. Slave team controller.

- Assumptions

- waypoint generation procedure produces feasible intervals for waypoints
  - maneuver controllers produce ensured results

- Theorem: T and S are bi-similar

Figure 4. The master team controller is the parallel composition of three transition systems.

- Team controllers abstract the behavior of each vehicle

- composition with supervisor and maneuver controller

# Path coordination for 2 vehicles

- Vehicle  $v_1$ 
  - Find the optimal path from  $\alpha$  to  $\gamma$
  - Path cost is reduced when the position of  $v_1$  coincides with the position of  $v_2$
- Vehicle  $v_2$ 
  - Departs from  $\beta$  and has to return to  $\beta$
  - Has a limited amount of fuel  $\Theta$
- Operational constraints
  - If  $v_1$  and  $v_2$  meet at some point then separation occurs only when  $v_2$  has to return to  $\beta$  (due to fuel constraints)

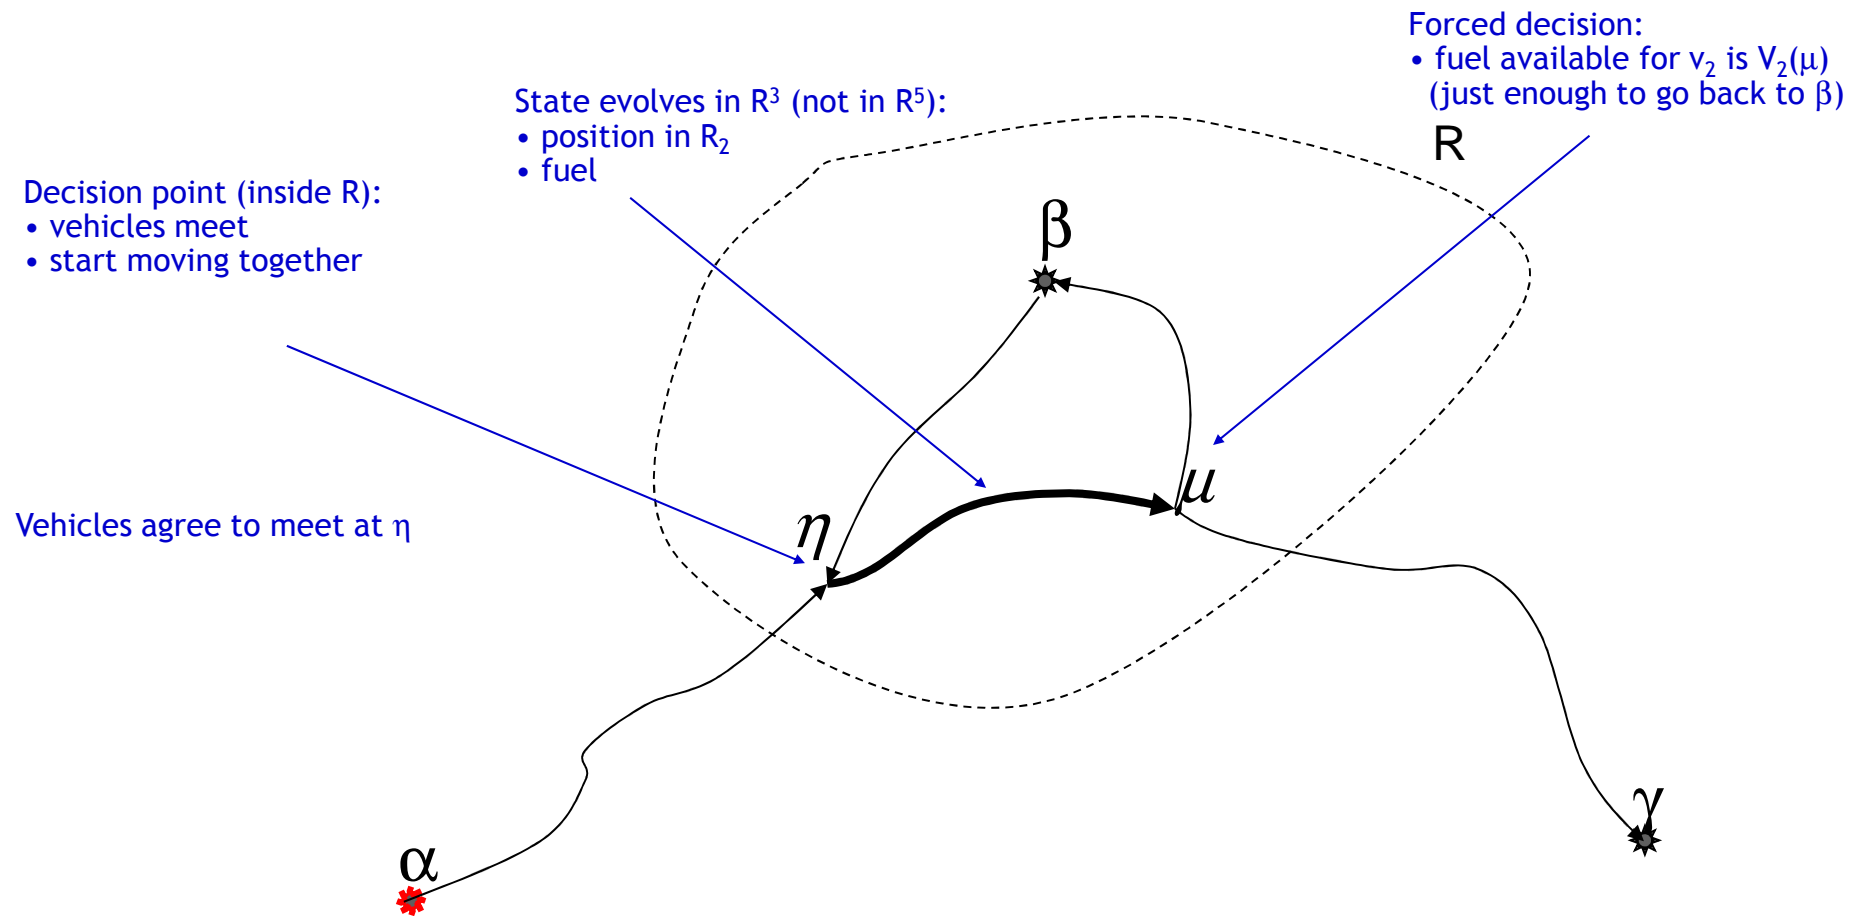

# Related work

- Branicky (1999) extended the Fast Marching Method to optimal hybrid control problems:
  - Stair climbing problem: optimal to reach any position of a building with multiple floors. Each floor is connected to its neighboring floors by stairs. Floors correspond to discrete states, stairs correspond to transitions with fixed cost.
  - Very simple dynamics.
- Sethian<sup>1</sup> (2002) introduced motion coordination problems to illustrate the use of Ordered Upwind Methods for solving optimal hybrid control applications
  - Find an optimal trajectory for a person walking on a varied landscape and carrying a pair of inline roller skates (option to switch between walking and skating by paying a time penalty)
    - Modeled with two discrete states, thus requiring two copies of the same continuous-time state-space
    - Problem solved with the one value function defined on the hybrid state-space.

# Structure of solution

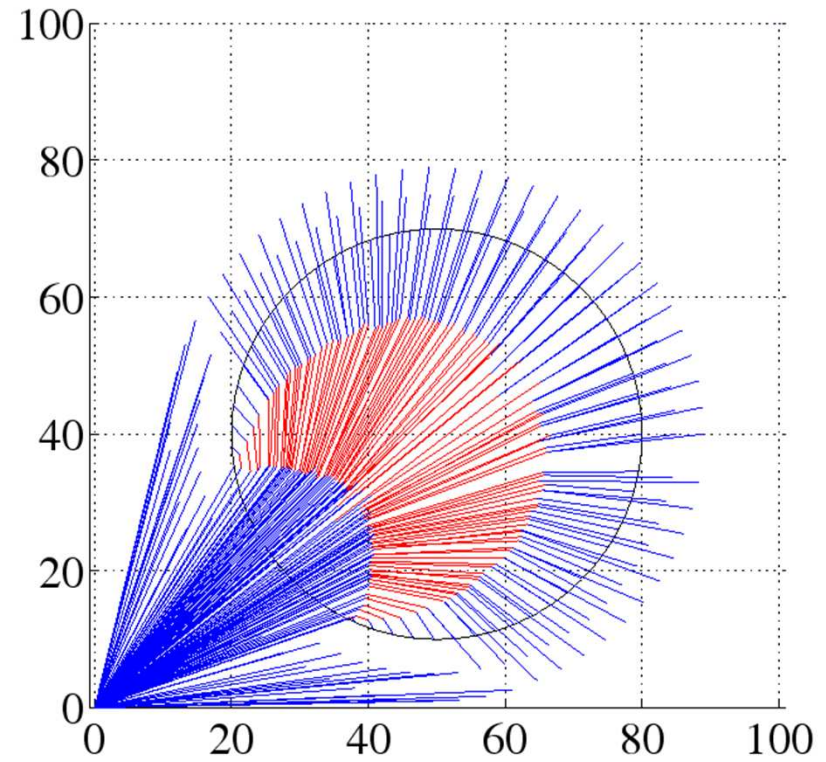

- The integral constraint is converted to a state-constraint involving the value function  $V_2$ . This restricts the set of feasible controls so that we can apply dynamic programming.

- P. Soravia, *Viscosity solutions and optimal control problems with integral constraints*, *Systems & Control Letters* 40 (2000) 325-335

# Value function approach

It is optimal to coordinate

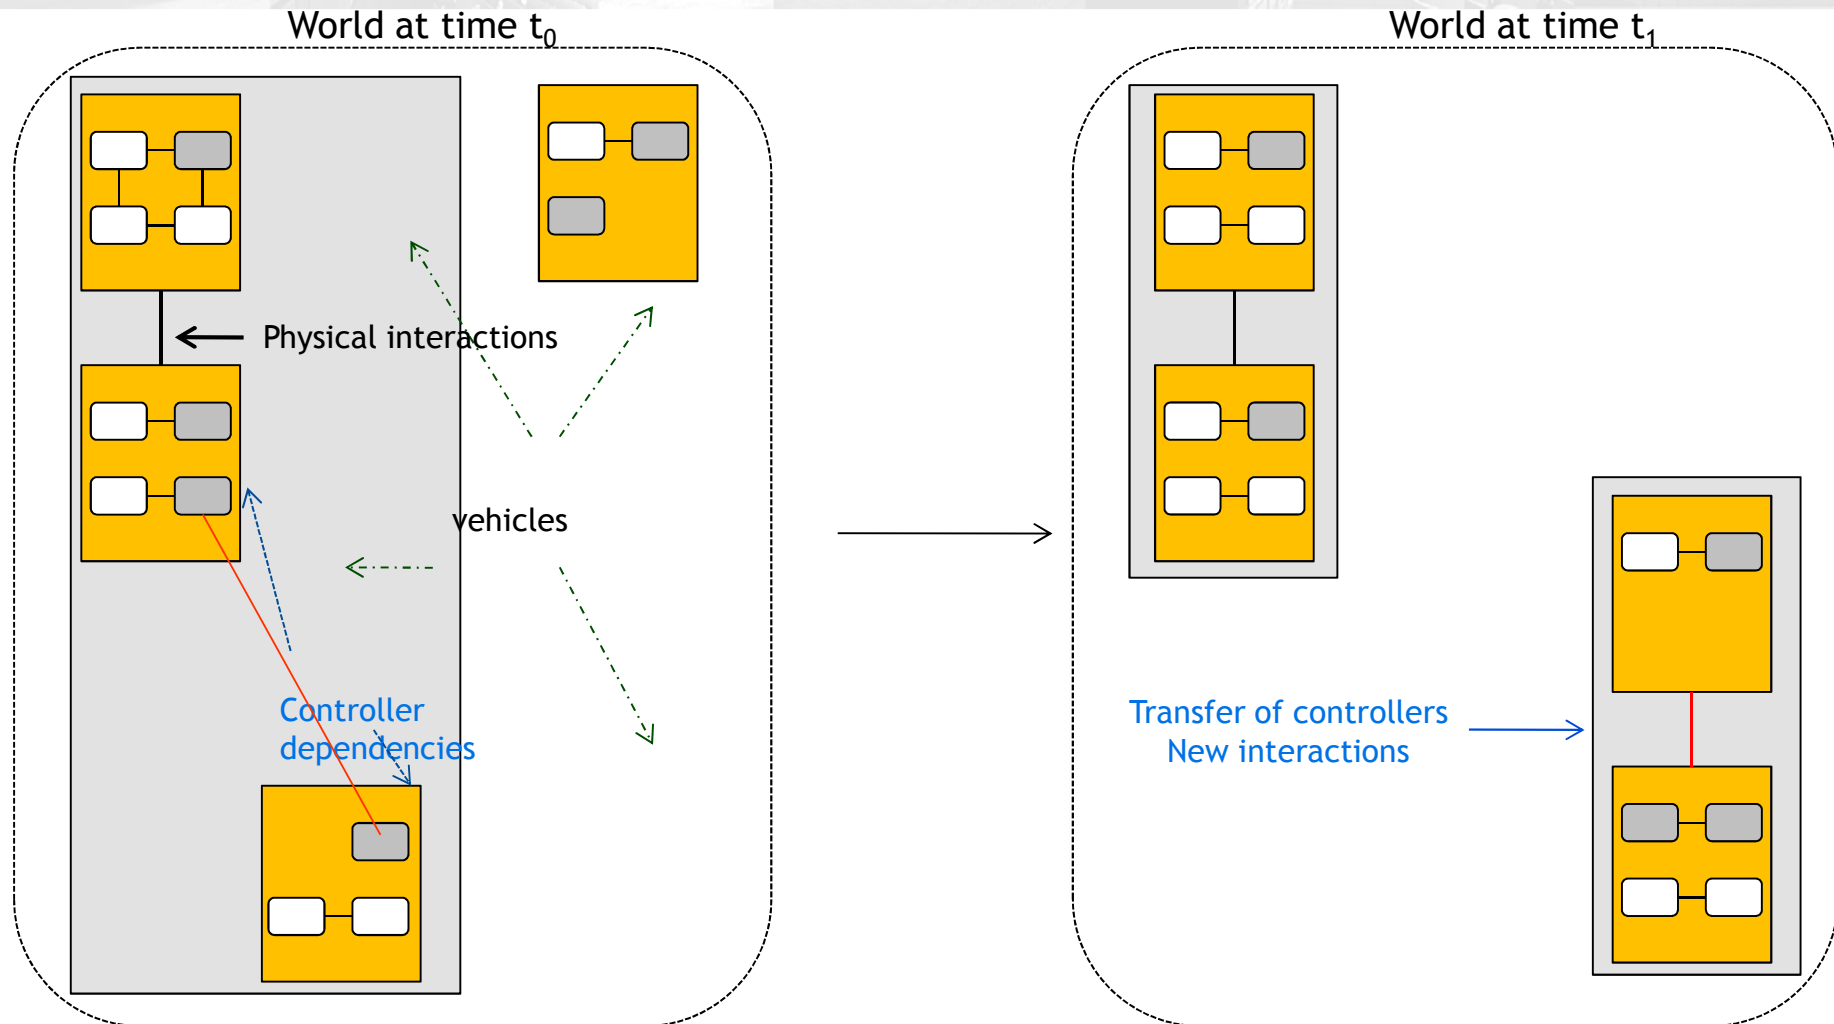

# WHAT ARE WE MISSING?

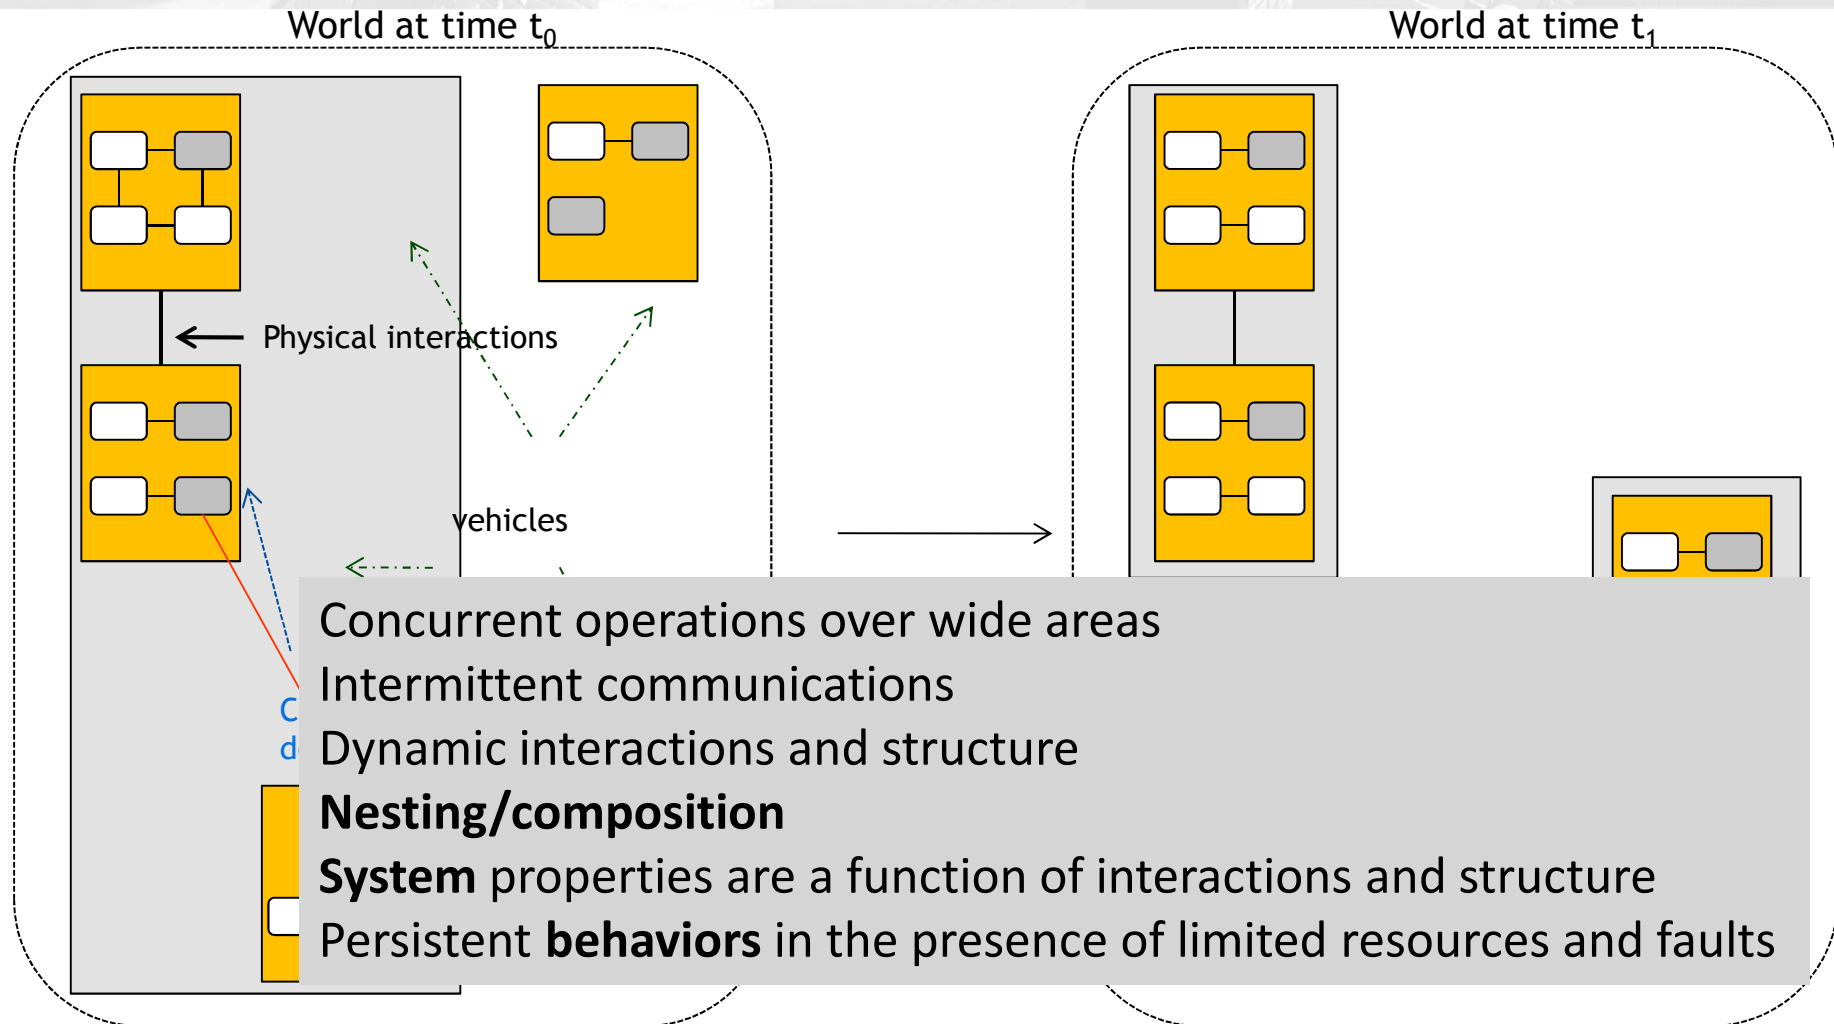

# Simulink analogy...

Embed blocks in a 3 dimensional space; let blocks move according to laws of motion  
World is partially known due to sensor and communication limitations; this leads to intermittent interactions

# Simulink analogy...

Embed blocks in a 3 dimensional space; let blocks move according to laws of motion

World is partially known due to sensor and communication limitations; this leads to intermittent interactions

# System's view

- What is the state(s) of the system?
- What are the dynamics?
- How do we specify system's behavior?
- What new behaviors can be specified?

# MODELLING CHALLENGES

# Two types of entities

- Physical entities
  - Host computational entities (computational environment)
  - Provide sensing and comms capabilities to computational entities
  - Dynamics depend on physical interactions with other physical entities and the environment (laws of physics)
  - Actions may affect other physical entities and the environment
  - Composable
- Computational entities (e.g., controllers)
  - Reside on physical entities
  - Allowed to migrate through communication channels
  - Dynamics depend on interactions with other local or remote physical entities (laws of computation)
  - Composable

# Set-valued state and coupled dynamics

- State of physical entities
  - Motion
  - List of physical resources
  - List of computational entities
  - List of available communication channels
  - List of physical interactions
- Controls
  - Motion
  - Manage local resources
  - Modify the environment
  - Compose
- State of computational entities
  - Location
  - List of computational interactions
  - Internal state
- Controls
  - Migrate
  - Enable/disable communication channels of physical entities (permissions)
  - Establish/delete interactions
  - Compose
  - Internal

# Dynamic reconfiguration

“Dynamic reconfiguration is a common feature of communicating systems.

The notion of link, not as a fixed part of the system but as a datum that we can manipulate, is essential for understanding such systems.

What is the mathematics of linkage?

The theories of computation are evolving from notions like value, evaluation and function to those of link, interaction and process.”

Milner, 1999

# Bigraphs (Milner 2008)

## The 'bi-' structure of a bigraph

Bigraphical reaction rules  
Lacks dynamic systems' view

# CONTROL (?) CHALLENGES

# Specifications

- “Traditional” specifications for an augmented state-space
  - Invariance
  - Attainability
  - Optimality
- Examples
  - A computational entity should remain in a given region independently of the physical entity where it resides.
  - At least of vehicle of a given type remains in a given region.
  - A structure of vehicles and controllers remains in a given region to provide a region-wide service.
  - A structure of vehicles and controllers should attain a given state.

# Why is it difficult?

- Lack of global controllers
- Partial information setting
- Complex state-spaces and controls
- Permissions for communicating and interacting
- Spatial rendezvous for coordination
- Computational entities can be created/deleted on the fly
- Network effects
- Dynamic programming principle may not apply

**Controlling to compute and computing to control**

A satellite-style image of the North Atlantic Ocean, showing the outlines of North America, Europe, and the British Isles. The water is a deep blue, and the landmasses are visible in shades of green and brown. The text 'Conclusions' is overlaid in white on the left side of the image.

# Conclusions

Work at the intersection of computation and control

Developments should be evaluated and tested in real systems

Inspiration comes from networked vehicles but applicable to other domains

Provides food for thought???
